

**Supplemental Figure 1:** Figure supplement to Figure 1A. **Peptide synthesis quality control.** ESI-MS (positive mode) spectra of synthesised modified peptides with cysteine.  $m/z$  – mass per charge in Dalton.

**Supplemental Figure 2:** Figure supplement to Figure 1B and C. **(A)** Extended panel showing a wider range of starPEG(KA7)<sub>4</sub>-TAMRA (*upper row*) bound to Atto647N-labelled microtubules (*lower row*). **(B)** High contrast versions of selected images shown in Figure 1B and C.

**Supplemental Figure 3:** Figure supplement to Figures 1B and D. **Ionic strength and pH-dependency of starPEG-(KA7)<sub>4</sub>-TAMRA microtubule association.** Binding of starPEG-(KA7)<sub>4</sub>-TAMRA to taxol stabilised Atto647N-labelled microtubules at the indicated ionic strength (*left block*) and pH (*right block*) conditions. Each picture pair shows tubulin (*left*) and starPEG-(KA7)<sub>4</sub>-TAMRA (*right*) at the respective conditions given *on the left* (ionic strength in mM or pH value) or by the exact buffer conditions *on the right* of each picture pair. *Graphs at the bottom* of each column depict the starPEG-(KA7)<sub>4</sub>-TAMRA intensity values per  $\mu\text{m}$  microtubule as a function of the ionic strength (*left*) or pH value (*right*). Averages of three independent flow channels (each 50-100 quantified microtubules) are shown. *Orange and purple lines* are exponential decay fits.

**Supplemental Figure 4:** Figure supplement to Figure 1E. **Subtilisin treatment controls.** **(A)** 4-12% SDS-PAGE gel showing the non-treated (*left*) and the subtilisin-treated microtubule preparation (*right*) used for the binding-assay shown in Figure 1E. Proteins are indicated *on the right*, subscript 's' indicates subtilisin treated tubulin. Assignment according to (Alper et al., 2014). **(B)** starPEG-(KA7)<sub>4</sub>-TAMRA (*mid and cyan in overlay on the right*) binding to (non-treated) brightly Atto647N-labelled GMP-CPP/taxol stabilised and dimly Atto647N-labelled GTP/taxol stabilised microtubules (*left and red in overlay on the right*). Arrowheads indicate bright GMP-CPP microtubules next to dim GTP microtubules, for easy comparison of bound starPEG-(KA7)<sub>4</sub>-TAMRA.

**Supplemental Figure 5:** Figure supplement to Figure 2 D and E. **Expansion of end-tracking starPEG-(KA7)<sub>4</sub>-TAMRA onto the newly polymerised microtubule lattice after rescue.** **(A)** kymographs showing dynamic microtubules (*upper left*), associated starPEG-(KA7)<sub>4</sub>-TAMRA (*lower left*), an intensity heatmap for bound starPEG-(KA7)<sub>4</sub>-TAMRA (*upper right*) and a scheme indicating the behaviour of starPEG-(KA7)<sub>4</sub>-TAMRA separated by rescue and catastrophe events (*lower right*). **(B)** (*left*) scheme indicating the parameters measured to calculate the graph on the (*right*). *Graph* showing the development of the starPEG-(KA7)<sub>4</sub>-TAMRA intensity on the core microtubule (i.e., microtubule at the time of rescue,  $t=0\text{s}$  – *orange squares and linear fit*), the microtubule extension (i.e., newly polymerised microtubule after rescue – *green circles and linear fit*), the total microtubule (i.e., core + extension, *magenta triangles and linear fit*) and on a starPEG-(KA7)<sub>4</sub>-TAMRA (i.e., equilibrated control section  $>2\mu\text{m}$  distal to the plus end at  $t=0\text{s}$  – *black inverted triangle and linear fit*) as a function of the time after rescue (i.e.,  $t=0\text{s}$ ). Intensity values per  $\mu\text{m}$  microtubule were normalised to the core intensity at  $t=0\text{s}$ . Averages of 13 rescue events are shown. The slope  $\pm$  standard error of the respective linear fits are given.

**Supplemental Figure 6:** Figure supplement to Figure 4. **(A)** Stills of Supplemental Movies 5.1-5.3 showing additional events of starPEG-(KA7)<sub>4</sub>-TAMRA-mediated pulling of intersecting microtubules by depolymerising microtubule plus ends. In contrast to Figure 4A only the Alexa647-tubulin signal is shown, but now at 1s time resolution. Supplemental Movies 5.1 and 5.2 show examples for two consecutive pulling events by the same depolymerising microtubule. *Blue arrowheads* indicate the start of individual pulling events. **(B)** *Top panel row:* Stills showing the microtubule geometries during a starPEG-(KA7)<sub>4</sub>-TAMRA-mediated pulling event. *White dashed box* indicates the area ('l') that is used in a 4-fold magnification for the *overlay on the bottom*, depicting the measurements made to calculate the bending forces that applied during pulling events (*please refer to 'results' section for a detailed*

description). Graph on the right summarises calculated corrected bending forces for deflection angles  $\leq 30^\circ$ . Horizontal bar indicates median.

**Supplemental Figure 7:** Figure supplement to Figure 5B. Stills of Supplemental Movies 6.1-6.3 showing additional events of starPEG-(KA7)<sub>4</sub>-TAMRA-mediated microtubule-zippering. In contrast to Figure 5B only the Alexa647-tubulin signal is shown, but now at 1s time resolution. *Blue arrowheads* indicate the interacting microtubules prior to bundling, *white arrowheads* the resulting overlaps.

**Supplemental Figure 8: Schematics depicting possible applications for starPEG-(KA7)<sub>4</sub> derived constructs.** (A) *Dynamic and reversible fluorescence-labelling of microtubules in vitro.* Microtubule labelling by starPEG-(KA7)<sub>4</sub> is robust, reversible and shows a good signal-to-noise ratio even in the presence of free tubulin due to a  $K_d$  in the low nanomolar range. At low concentrations, starPEG-(KA7)<sub>4</sub> can also be used in classical *in vitro* reconstitution experiments together with recombinant molecular motors or MAPs, as it does not significantly alter their behaviour on the microtubule lattice. StarPEG-(KA7)<sub>4</sub> can even be used to label dynamic microtubules with the caveats that i) microtubule growth rates are increased in its presence and ii) labelling of the growing plus end might be inefficient at lower starPEG-(KA7)<sub>4</sub> concentrations, as peptides are not able to track the growing end. For experiments that require a non-disturbed microtubule lattice, visualising microtubule by fluorescent starPEG-(KA7)<sub>4</sub> represents a good alternative to the stochastic covalent labelling of tubulin dimers with fluorescent dyes, which might result in lattice defects. In the current form, starPEG-(KA7)<sub>4</sub> is not suitable for *in vivo* applications, as it lacks selectivity towards other biomolecules with a negative surface charge (DNA, lipid bilayers) and cell permeability. (B) *Reversible physical and electrical screening of microtubules in vitro.* Our experiments further suggest that higher amounts of starPEG-(KA7)<sub>4</sub> on the microtubule lattice, impede the lattice association of motor proteins or the addition of tubulin dimers to the microtubule ends. Thus starPEG-(KA7)<sub>4</sub>, could be used for (*in vitro*) applications that require to (reversibly) shield the microtubule lattice from physical or chemical interactions, selectively shut down lattice-dependent tubulin biology or to mask the negatively-charged microtubule lattice (fully decorated lattices are expected to be neutral to positively-charged). (C) *Targeting of modifying enzymes to the microtubule lattice in vitro.* starPEG-(KA7)<sub>4</sub> could be fused to any modifying enzyme of interest (e.g., kinases, phosphatases, acetylases, etc.) to target the enzyme to the microtubule lattice. Using non-tubulin-specific enzymes one could provoke non-natural modification patterns on the microtubule lattice. Fusing starPEG-(KA7)<sub>4</sub> to *bona fide* tubulin modifying enzymes might enhance their dwell time on the microtubule lattice thereby increasing the grade of modification. Translating the features of starPEG-(KA7)<sub>4</sub> into a linear geometry with protein (instead of PEG) linkers, this concept could be adopted for *in vivo* studies, probably provoking strong phenotypes that for example would facilitate examinations on the effect of posttranslational tubulin modifications on microtubule stability. (D) *Modifying the processivity of molecular motors.* Kinesins often feature a N-terminal extension preceding the actual motor domain. These extensions are involved in cargo binding (kinesin-3 (Gruneberg et al., 2006) and kinesin-7 (Drechsler et al., 2015; Roberts et al., 2014)), force generation (kinesin-1 (Khalil et al., 2008)) or microtubule association (kinesin-5 (Britto et al., 2016; Stock et al., 2003) and kinesin-7 (Drechsler et al., 2015)). In analogy to the kinesins-5 and -7, virtually any kinesin could be engineered with N-terminal or C-terminal (for minus end directed kinesins) (KA)<sub>n</sub> repeat extensions to increase their microtubule landing rates and processivity. This effect would be tuneable by the number of KA repeats and could convert non-processive kinesins, like kinesin-14, into highly processive ones. (E) *Microtubules as basis for plasmonic waveguides.* Microtubules self-assemble *in vitro* into stiff filaments with 25 nm diameter and several micrometre lengths. Given their high regularity on the nanoscale as well as the robustness and cost-effectiveness in their generation, microtubules are attractive candidates as template structures for material synthesis (Kirsch et al., 1997). Using starPEG-(KA7)<sub>4</sub> as linker, it will be conceivable to densely pack metal-nanoparticles onto the outer surface of microtubules in pursuit of mass-producing functional nanostructures, such as plasmonic waveguides (Gür et al., 2016). (F) *Measuring depolymerisation-coupled pulling forces in vivo.* Magnetic beads coated with starPEG-(KA7)<sub>4</sub> that are injected into mitotic cells and moved by magnetic tweezers to the mitotic spindle midzone would

eventually become attached to dynamic spindle microtubules. During depolymerisation phases, these beads would become end-on attached and could be used to measure *in vivo* microtubule-dependent depolymerisation-coupled pulling forces during metaphase and anaphase with a force-calibrated magnetic tweezer (Garzon-Coral et al., 2016).

**Supplemental Movie 1:** Behaviour of starPEG-(KA7)<sub>4</sub>-TAMRA (50 nM) on dynamic microtubules. Please note the accumulation of starPEG-(KA7)<sub>4</sub>-TAMRA on the microtubule lattice during depolymerisation indicated by an intensity increase of the TAMRA-signal.

**Supplemental Movie 2:** Microtubule nucleation in the absence/presence of the indicated peptides at the given concentrations. Behaviour of starPEG-(KA7)<sub>4</sub>-TAMRA (50 nM) on dynamic microtubules. Please note that a rigor kinesin-1 mutant was used to immediately surface immobilise nucleated microtubules.

**Supplemental Movie 3:** Collage of 3 movies (3.1-3.3) showing the depolymerisation coupled pulling of intersecting dynamic microtubules cross-linked by 50 nM starPEG-(KA7)<sub>4</sub>-TAMRA. *Left column* shows the starPEG-(KA7)<sub>4</sub>-TAMRA signal only, the *column on the right* starPEG-(KA7)<sub>4</sub>-TAMRA (cyan) superimposed on the tubulin signal (red). See also Figure 4 and Supplemental Movie 5.

**Supplemental Movie 4:** Collage of 3 movies (4.1-4.3) showing bundling of dynamic microtubules by 50 nM starPEG-(KA7)<sub>4</sub>-TAMRA. *Left column* shows the starPEG-(KA7)<sub>4</sub>-TAMRA signal only, the *column on the right* starPEG-(KA7)<sub>4</sub>-TAMRA (cyan) superimposed on the tubulin signal (red). See also Figure 5 and Supplemental Movie 6. *Blue arrowheads* indicate microtubules before bundling, *white arrowheads* the final microtubule overlap.

**Supplemental Movie 5:** Collage of 3 movies (5.1-5.3) showing the depolymerisation coupled pulling of intersecting dynamic microtubules cross-linked by 50 nM starPEG-(KA7)<sub>4</sub>-TAMRA at a three-fold better time resolution as compared to Movie 3. Only the starPEG-(KA7)<sub>4</sub>-TAMRA signal is shown. *Blue arrowheads and writing* indicate single pulling events. Please note that the same starPEG-(KA7)<sub>4</sub>-TAMRA carrying depolymerising microtubule plus end can perform multiple sequential pulling events on different intersecting microtubules. See also Movie 3 and Supplemental Figure 6A.

**Supplemental Movie 6:** Collage of 3 movies (6.1-6.3) showing bundling of dynamic microtubules by 50 nM starPEG-(KA7)<sub>4</sub>-TAMRA at a three-fold better time resolution as compared to Movie 4. Only the starPEG-(KA7)<sub>4</sub>-TAMRA signal is shown. *Blue arrowheads* indicate single zippering events, *white arrowheads* the final microtubule overlap. See also Movie 4 and Supplemental Figure 7.
