LÉVY PROCESSES, MARTINGALES AND UNIFORM INTEGRABILITY

DAVID BERGER, FRANZISKA KÜHN, AND RENÉ L. SCHILLING

ABSTRACT. We give equivalent conditions for the existence of generalized moments of a Lévy process $(X_t)_{t\geq 0}$. We show, in particular, that the existence of a generalized g-moment is equivalent to uniform integrability of $(g(X_t))_{t\in[0,1]}$. As an application, it turns out that certain functions of a Lévy process which are integrable and local martingales are already true martingales.

A *generalized moment* of a stochastic process $(X_t)_{t\geq 0}$ is an expression of the form $\mathbb{E}\,[g(X_t)]$. Such moments arise naturally when studying Markov semigroups. For Lévy processes, a necessary and sufficient condition based on the jumps and the integrability properties of the jump measure of the process is known (see Section 1). We will give a new proof of this result and add a few useful further equivalent conditions; in particular, $\mathbb{E}\,[g(X_t)]$ exists if, and only if, $g(X_t)$ is uniformly integrable for bounded t-sets. Our arguments are based on Gronwall's lemma and this technique can also be used (see Section 2) to show that certain functions of a Lévy process $(f(X_t))_{t\geq 0}$ which are both a local martingale and integrable, i.e. $\mathbb{E}|f(X_t)| < \infty$, are already proper martingales. In the last section (Section 3) we apply our results to get a short proof of the characterization of infinitely divisible lattice distributions and a 'martingale' criterion for the transience of Lévy processes.

Let us recall a few key concepts and techniques which will be needed later on. Most of our notation is standard or self-explanatory; in addition, we use $|x|_{\ell^p}^p := \sum_{k=1}^d |x_k|^p$ with the usual modification if $p = \infty$. We write $\|f\|_{L^1(\mathbb{R}^d,g)} := \int_{\mathbb{R}^d} |f(x)|\, g(x)dx$ for the weighted L^1-norm (with positive and measurable weight function $g : \mathbb{R}^d \to [0,\infty)$) and $L^1(\mathbb{R}^d, g) := \{f : \mathbb{R}^d \to \mathbb{R} \mid f \text{ measurable and } \|f\|_{L^1(\mathbb{R}^d,g)} < \infty\}$.

Lévy processes. A Lévy process $X = (X_t)_{t\geq 0}$ is a stochastic process with values in $\mathbb{R}^d$, stationary and independent increments and right-continuous sample paths with finite left-hand limits (càdlàg). Our standard references for Lévy processes are Sato [9] (for probabilistic properties) and Jacob [4] and [5] (for analytic aspects). It is well-known that a stochastic process X is a Lévy process if it has càdlàg paths and if its conditional characteristic function is of the form

$$\mathbb{E}\left[\mathrm{e}^{\mathrm{i}\xi\cdot(X_t-X_s)} \mid \mathscr{F}_s\right] = \mathrm{e}^{-(t-s)\psi(\xi)}, \quad 0 \leq s \leq t,\ \xi \in \mathbb{R}^d,$$

where $\mathscr{F}_s = \sigma(X_r, r \leq s)$ is the natural filtration of X. The *characteristic exponent* $\psi : \mathbb{R}^d \to \mathbb{C}$ is uniquely determined by the *Lévy–Khintchine formula*

$$\psi(\xi) = -\mathrm{i}b\cdot\xi + \frac{1}{2}Q\xi\cdot\xi + \int_{\mathbb{R}^d\setminus\{0\}} \left(1 - \mathrm{e}^{\mathrm{i}\xi\cdot x} + \mathrm{i}\xi\cdot x\mathbb{1}_{(0,1)}(|x|)\right)\nu(dx); \tag{1}$$

the *Lévy triplet* (b, Q, ν) where $b \in \mathbb{R}^d$, $Q \in \mathbb{R}^{d\times d}$ (a positive semidefinite matrix) and ν (a Radon measure on $\mathbb{R}^d \setminus \{0\}$ such that $\int_{\mathbb{R}^d\setminus\{0\}} \min\{|x|^2, 1\}\,\nu(dx) < \infty$) uniquely describe ψ.

Using the characteristic exponent we can determine the infinitesimal generator A of the process X either as *pseudo-differential operator*

$$Au(x) = -\psi(D)u(x) = \mathcal{F}^{-1}[-\psi\mathcal{F}u](x), \quad u \in \mathcal{S}(\mathbb{R}^d),$$

where $\mathcal{F}u(\xi) = (2\pi)^{-d}\int_{\mathbb{R}^d} \mathrm{e}^{-\mathrm{i}\xi\cdot x}u(x)\,dx$ is the Fourier transform and $\mathcal{S}(\mathbb{R}^d)$ is the Schwartz space of rapidly decreasing smooth functions, or as integro-differential operator

$$Au(x) = Lu(x) + Ju(x) + Ku(x) \tag{2}$$

where L, J and K are again linear operators: L is the local part, J takes into account the small jumps and K the large jumps, i.e.

$$\begin{aligned} Lu(x) &= b\cdot\nabla u(x) + \frac{1}{2}\nabla\cdot Q\nabla u(x),\\ Ju(x) &= \int_{0<|y|<1} (u(x+y) - u(x) - y\cdot\nabla u(x))\,\nu(dy),\\ Ku(x) &= \int_{|y|\geq 1} (u(x+y) - u(x))\,\nu(dy). \end{aligned}$$

The precise form of the domain $\mathcal{D}(A)$ of A (as closed operator on the Banach space of continuous functions vanishing at infinity $(C_\infty(\mathbb{R}^d), \|\cdot\|_\infty)$) is not known; but both the test functions $C_c^\infty(\mathbb{R}^d)$ and the Schwartz spaces $\mathcal{S}(\mathbb{R}^d)$ are operator cores. On the other hand, the expression (2) has a pointwise meaning for every $g \in C^2(\mathbb{R}^d)$ and we will continue to use the notation $Ag(x)$ despite the fact that $C^2(\mathbb{R}^d) \not\subset \mathcal{D}(A)$.

The *transition semigroup* $(P_t)_{t\geq 0}$ corresponding to the generator A or the process X is given by $P_t u(x) = \mathbb{E}\,[u(x + X_t)]$. Its adjoint, $P_t^* u(x) = \mathbb{E}\,[u(x - X_t)]$ is the transition semigroup of the Lévy process $-X = (-X_t)_{t\geq 0}$.

Dynkin's formula. Let $(X_t)_{t\geq 0}$ be a Lévy process and denote by $\mathcal{F}_t = \sigma(X_s, s \leq t)$ its natural filtration and $(A, \mathcal{D}(A))$ the infinitesimal generator. Dynkin's formula states that for every $u \in \mathcal{D}(A)$ and every stopping time σ with $\mathbb{E}\,[\sigma] < \infty$ we have

$$\mathbb{E}\,[u(X_\sigma + x)] - u(x) = \mathbb{E}\left[\int_{[0,\sigma)} Au(X_s)\,ds\right]. \tag{3}$$

There are several ways to prove this result, e.g. using arguments from potential theory (as in [12, Proposition 7.31]), semigroup theory (as in [8, Proposition VII.1.6]) or by Itô's formula. At the heart of the argument is the fact that

$$M_t^{[u]} := u(X_t + x) - u(x) - \int_{[0,t)} Au(X_s)\,ds, \quad u \in \mathcal{D}(A), \tag{4}$$

is an $\mathcal{F}_t$-martingale combined with a stopping argument. There are various ways to extend the class of functions u for which we have some kind of Dynkin's formula. It is clear that formula (3) can be extended to those functions u such that $u(X_\sigma) \in L^1(\mathbb{P})$ and $Au(X_{s\wedge\sigma}) \in L^1(ds\otimes\mathbb{P})$. Such moment estimates will be given below.

Here we need a *Dynkin inequality* which we are going to prove for positive $g \in C^2(\mathbb{R}^d)$.

Lemma 1 (Dynkin's inequality). *Let $(X_t)_{t\geq 0}$ be a Lévy process with generator $(A, \mathcal{D}(A))$ and extend A using* (2) *to $C^2(\mathbb{R}^d)$. For every $g \in C^2(\mathbb{R}^d)$ satisfying $g(x) \geq 0$ and every stopping*

time σ the following inequality holds

$$\mathbb{E}g(X_{t\wedge\sigma}) \le g(0) + \mathbb{E}\left[\int_{[0,t\wedge\sigma)} |Ag(X_s)|\,ds\right]. \tag{5}$$

Proof. Pick a cut-off function $\chi_R \in C^\infty(\mathbb{R}^d)$ such that $\mathbb{1}_{\overline{B}_{R+1}(0)} \le \chi_R \le \mathbb{1}_{\overline{B}_{R+2}(0)}$ for some $R > 0$. Since $g\chi_R \in C_c^2(\mathbb{R}^d)$ we know that $g\chi_R \in \mathcal{D}(A)$, and we see that for any stopping time σ the process $\left(M_{t\wedge\sigma}^{[g\chi_R]}\right)_{t\ge 0}$ is a martingale, hence

$$\mathbb{E}\left[(g\chi_R)(X_{t\wedge\sigma})\right] - g(0) = \mathbb{E}\left[\int_{[0,t\wedge\sigma)} A(g\chi_R)(X_s)\,ds\right]. \tag{6}$$

If we replace σ by the stopping time $\sigma\wedge\tau_R$ where $\tau_R = \inf\{s\ge 0 \mid |X_s|\ge R\}$, then we can use the fact that $|X_s|\le R$ if $s\in[0,t\wedge\sigma\wedge\tau_R)$. This implies, in particular, that $\partial^\alpha(g\chi_R)(X_s) = \partial^\alpha g(X_s)$, and we see from the integro-differential representation (2) of A that

$$\begin{aligned} A(g\chi_R)(X_s) &= L(g\chi_R)(X_s) + J(g\chi_R)(X_s) + K(g\chi_R)(X_s)\\ &= b\cdot\nabla g(X_s) + \frac{1}{2}\nabla\cdot Q\nabla g(X_s) + \int_{0<|y|<1} (g(X_s+y) - g(X_s) - y\cdot\nabla g(X_s))\,\nu(dy)\\ &\quad + \int_{|y|\ge 1} ((g\chi_R)(X_s+y) - g(X_s))\,\nu(dy); \end{aligned} \tag{7}$$

for the second equality observe that $|X_s|\le R$, $|X_s+y|\le R+1$ for $|y|<1$ and that L is a local operator. Since g is positive, hence $g\chi_R\le g$, we conclude that $A(g\chi_R)(X_s)\le Ag(X_s)$. Inserting this into (6) gives

$$\mathbb{E}\left[(g\chi_R)(X_{t\wedge\sigma\wedge\tau_R})\right] - g(0) \le \mathbb{E}\left[\int_{[0,t\wedge\sigma\wedge\tau_R)} Ag(X_s)\,ds\right] \le \mathbb{E}\left[\int_{[0,t\wedge\sigma)} |Ag(X_s)|\,ds\right].$$

Since $g\ge 0$, we can use Fatou's lemma on the left-hand side and get (5). □

Friedrichs mollifiers. Let $j : \mathbb{R}^d \to [0,\infty)$ be a C^∞-function with compact support $\operatorname{supp} j \subset \overline{B}_1(0)$ such that $j(x)$ is rotationally symmetric and $\int j(x)\,dx = 1$. For every $\epsilon > 0$ we define $j_\epsilon(x) := \epsilon^{-d} j(x/\epsilon)$, i.e. j_ϵ is again smooth, rotationally symmetric and satisfies $\operatorname{supp} j_\epsilon \subset \overline{B}_\epsilon(0)$ and $\int j_\epsilon(x)\,dx = 1$. For any locally bounded function $g : \mathbb{R}^d \to \mathbb{R}$ the convolution

$$g^\epsilon(x) := j_\epsilon * g(x) := \int g(x-y) j_\epsilon(y)\,dy, \quad x\in\mathbb{R}^d,$$

exists and defines a C^∞-function. Moreover, $\operatorname{supp} g^\epsilon \subset \operatorname{supp} g + \operatorname{supp} j_\epsilon \subset \operatorname{supp} g + \overline{B}_\epsilon(0)$. The function g^ϵ is called *Friedrichs regularization* of g.

Submultiplicative functions. A function $g : \mathbb{R}^d \to [0,\infty)$ is said to be *submultiplicative* if there exists a constant $c = c(g) \in [1,\infty)$ such that

$$\forall x, y \in \mathbb{R}^d \ : \ g(x+y) \le c g(x) g(y).$$

In order to avoid pathologies, we consider only measurable submultiplicative functions.([1]) Every locally bounded submultiplicative function grows at most exponentially, i.e. there are constants $a, b \in (0,\infty)$ such that $g(x) \le a\mathrm{e}^{b|x|}$. Since $1+g$ inherits submultiplicativity from g, we may assume that $g\ge 1$. The following lemma shows that we can even assume that a submultiplicative function is smooth.

([1])An example of a non-measurable submultiplicative function is $g(x) = \mathrm{e}^{a(x)}$, $x\in\mathbb{R}$, where a is a non-measurable solution to the functional equation $a(x+y) = a(x) + a(y)$.

Lemma 2. *Let g be a locally bounded submultiplicative function and g^ϵ its Friedrichs regularization. Then $g^\epsilon \in C^\infty$ is submultiplicative and it satisfies*

$$\forall x \in \mathbb{R}^d \ : \quad c_\epsilon^{-1} g(x) \le g^\epsilon(x) \le c_\epsilon g(x) \tag{8}$$

for some constant $c_\epsilon = c_{\epsilon,g}$.

Proof. Submultiplicativity follows immediately from the two-sided estimate (8):

$$g^\epsilon(x+y) \le c_\epsilon g(x+y) \le c_\epsilon c g(x) g(y) \le c_\epsilon^3 c g^\epsilon(x) g^\epsilon(y).$$

In order to see (8), we use the definition of g^ϵ and fact that g is submultiplicative,

$$g^\epsilon(x) = \int g(x-y) j_\epsilon(y)\,dy \le c g(x) \int g(-y) j_\epsilon(y)\,dy \le c \sup_{|y|\le\epsilon} g(y) g(x)$$

and

$$g(x) = \int g(x) j_\epsilon(y)\,dy \le c \int g(x-y) g(y) j_\epsilon(y)\,dy \le c \sup_{|y|\le\epsilon} g(y) g^\epsilon(x). \qquad \square$$

1. Generalized moments and uniform integrability

Let $(X_t)_{t\ge0}$ be a Lévy process with triplet (b, Q, ν). The following moment result for a locally bounded submultiplicative functions g is well-known, cf. Sato [9, Theorem 25.3, p. 159]:

$$\mathbb{E}\,[g(X_t)] < \infty \text{ for some (hence, all) } t > 0 \iff \int_{|y|\ge1} g(y)\,\nu(dy) < \infty. \tag{9}$$

Our aim is to show that this is also equivalent to a certain uniform integrability condition. Although we cast the statement and proof for Lévy processes, an extension to certain Lévy-type processes is possible; see Remark 4 below. We denote by $\mathcal{T}$ be the family of stopping times for the process X equipped with its natural filtration.

Theorem 3. *Let $(X_t)_{t\ge0}$ be a Lévy process with generator A, transition semigroup $(P_t)_{t\ge0}$, and triplet (b, Q, ν), and let g be a locally bounded submultiplicative function. The following assertions are equivalent:*

a) $\mathbb{E}\,[g(X_t)]$ *exists and is finite for some (hence, all) $t > 0$;*
b) $\mathbb{E}\left[\sup_{s\le t} g(X_s)\right]$ *exists and is finite for some (hence, all) $t > 0$;*
c) $\{g(X_\sigma)\}_{\sigma\in\mathcal{T},\sigma\le t}$ *is uniformly integrable for every fixed $t > 0$;*
d) $\sup_{\sigma\in\mathcal{T},\sigma\le t} \mathbb{E}\,[g(X_\sigma)]$ *is finite for every fixed $t > 0$;*
e) $\int_{|y|\ge1} g(y)\,\nu(dy) < \infty$*;*
f) *The adjoint semigroup $P_t^* f(x) := \mathbb{E}\,[f(x - X_t)]$ is a strongly continuous operator semigroup on the weighted L^1-space $L^1(\mathbb{R}^d, g)$.*
g) *The adjoint generator $(A^*\phi)(x) := (A\phi)(-x)$ satisfies $A^*\phi \in L^1(\mathbb{R}^d, g)$ for all $\phi \in C_c^\infty(\mathbb{R}^d)$.*
h) *There exists a non-negative function $\phi \in C_c^\infty(\mathbb{R}^d)$, $\phi \not\equiv 0$, such that $A^*\phi \in L^1(\mathbb{R}^d, g)$.*

If one (hence, all) of the conditions is satisfied, then there are constants $c_i > 0$, $i = 1, 2, 3$, such that

$$\mathbb{E}[g(X_t)] \le c_1 \mathrm{e}^{c_2 t}, \qquad t \ge 0,$$

and

$$\|A^*\phi\|_{L^1(\mathbb{R}^d,g)} \le c_3 \left(|b|_{\ell^1} + |Q|_{\ell^1} + \int_{y\ne0} (1 \wedge |y|^2)\,\nu(dy) + \int_{|y|\ge1} g(y)\,\nu(dy) \right) \|\phi\|_{C_b^2(\mathbb{R}^d)}.$$

Remark 4. There is a further equivalent condition if $x \mapsto g(|x|)$ is locally bounded, submultiplicative and $g(r)$ is increasing:

i) $\mathbb{E}\left[g\left(\sup_{s\le t}|X_s|\right)\right] < \infty$ for some (hence, all) $t > 0$.

The direction i)⇒a) follows from the assumption that g is increasing. The implication b)⇒i) does not need monotonicity since we have

$$g\left(\sup_{s\le t}|X_s|\right) \le \sup_{s\le t} g\left(|X_s|\right)$$

at least if $x \mapsto g(|x|)$ is continuous. This can always be achieved by a Friedrichs regularization.

Let us also point out that we may replace A^* and P_t^* by A and P_t if either (the law of) X_t is symmetric or if g is even, i.e. $g(x) = g(-x)$.

The conditions d) (for deterministic stopping times), e), i) can be found in Sato [9, Chapter 25]; b) is due to Siebert [14] and variants of g), h) appear first in Hulanicki [3]; their proofs are cast in the language of probability on (Lie) groups. The streamlined proofs given in this paper are new.

Some of our arguments carry over to Lévy-type processes whose generators have bounded coefficients (see [1, p. 55] for the notation); in particular e)⇒a) (using the alternative proof below) ⇒b)⇒c)⇒d) becomes

$$\begin{aligned}\sup_{x\in\mathbb{R}^d}\int_{|y|\ge 1} g(y)\,\nu(x,dy) < \infty &\Rightarrow \sup_{x\in\mathbb{R}^d}\mathbb{E}^x[g(X_t - x)] < \infty\\ &\Rightarrow \sup_{x\in\mathbb{R}^d}\mathbb{E}^x[\sup_{s\le t} g(X_s - x)] < \infty\\ &\Rightarrow \{g(X_\sigma - x)\}_{\sigma\in\mathcal{T},\sigma\le t} \text{ is unif. integrable}\\ &\Rightarrow \sup_{\sigma\in\mathcal{T},\sigma\le t}\mathbb{E}^x[g(X_\sigma - x)] < \infty,\end{aligned}$$

while d)⇒e) only yields $\inf_{x\in\mathbb{R}^d}\int g(y)\,\nu(x,dy) < \infty$, and an additional condition of the type $\sup_{x\in\mathbb{R}^d}\int_{|y|\ge1} g(y)\,\nu(x,dy) \le C\inf_{x\in\mathbb{R}^d}\int_{|y|\ge1} g(y)\,\nu(x,dy)$ is needed to get equivalences; this is partly worked out in [6].

In order to prove this theorem, we need a few preparations.

Lemma 5. *Let g be a locally bounded submultiplicative function. If $(X_t)_{t\ge0}$ is a Lévy process, then*

$$\mathbb{E}\left[\sup_{s\le T} g(X_s)\right] = \kappa_T < \infty \quad \textit{implies} \quad \mathbb{E}\left[\sup_{s\le 2T} g(X_s)\right] \le \kappa_T(1 + c\kappa_T) < \infty$$

and

$$\mathbb{E}[g(X_t)] < \infty \textit{ for some } t > 0 \quad \textit{implies} \quad \mathbb{E}[g(X_t)] < \infty \textit{ for all } t > 0.$$

Proof. **1°** We have

$$\mathbb{E}\left[\sup_{s\le 2T} g(X_s)\right] \le \mathbb{E}\left[\sup_{s\le T} g(X_s)\right] + \mathbb{E}\left[\sup_{T\le s\le 2T} g(X_s)\right] = \kappa_T + \mathbb{E}\left[\sup_{s\le T} g(X_{s+T})\right].$$

Since g is submultiplicative, we see $g(X_{s+T}) \le cg(X_{s+T} - X_T)g(X_T)$; moreover, X_T and $(X_{s+T} - X_T)_{s\ge 0} \sim (X_s)_{s\ge 0}$ are independent,[2] and so

$$\begin{aligned}\mathbb{E}\left[\sup_{s\le T} g(X_{s+T})\right] &\le c\mathbb{E}\left[\sup_{s\le T} g(X_{s+T} - X_T)\right]\mathbb{E}\left[g(X_T)\right]\\ &\le c\mathbb{E}\left[\sup_{s\le T} g(X_s)\right]\mathbb{E}\left[g(X_T)\right] \le c\kappa_T^2.\end{aligned}$$

2° Let $t_0 > 0$ such that $\mathbb{E}[g(X_{t_0})] < \infty$. Using the Markov property we see that for any $s < t_0$

$$\mathbb{E}\left[g(X_{t_0})\right] = \mathbb{E}\left[g(X_{t_0} - X_s + X_s)\right] = \int_{\mathbb{R}^d} \mathbb{E}\left[g(X_s + y)\right]\mathbb{P}(X_{t_0-s} \in dy).$$

Thus, there is some y such that $\mathbb{E}\left[g(X_s + y)\right] < \infty$, and we conclude from the submultiplicative property that $\mathbb{E}\left[g(X_s)\right] \le cg(-y)\mathbb{E}\left[g(X_s + y)\right] < \infty$ for all $s \le t_0$. As before, we can now show that $\mathbb{E}\left[g(X_{2t_0})\right] < \infty$ and, by iteration, we see that $\mathbb{E}\left[g(X_t)\right] < \infty$ for all $t > 0$. □

Lemma 6. *Let g be a locally bounded submultiplicative function and denote by g^ϵ its regularization with a Friedrichs mollifier. If A is the generator of a Lévy process given by* (2)*, then*

$$|Ag^\epsilon(x)| \le C_\epsilon\left(|b|_{\ell^1} + |Q|_{\ell^1} + \int_{y\neq 0}\left(1\wedge|y|^2\right)\nu(dy) + \sup_{|y|\le 1} g(y) + \int_{|y|\ge 1} g(y)\,\nu(dy)\right)g(x).$$

Note that the constant C_ϵ appearing in Lemma 6 is, in general, unbounded as $\epsilon \to 0$.

Proof. Without loss of generality we can assume that $g \ge 1$. Otherwise we use $g+1$ instead of g and observe that $A(g+1)^\epsilon = A(g^\epsilon + 1) = Ag^\epsilon$. As in (2) we write $A = L + J + K$.

Observe that $|\partial^\alpha g^\epsilon(x)| \le c_{\alpha,\epsilon}g(x)$ holds for every multi-index $\alpha \in \mathbb{N}_0^d$. This follows from

$$\left|\partial^\alpha g^\epsilon(x)\right| = \left|(\partial^\alpha j_\epsilon) * g(x)\right| \le \int \left|\partial^\alpha j_\epsilon(y)\right| g(x-y)\,dy \le cg(x)\sup_{|y|\le\epsilon} g(y)\int\left|\partial^\alpha j_\epsilon(y)\right|dy.$$

We can now estimate the three parts of A separately. For the local part we use the above estimate with $|\alpha| = 1$ and $|\alpha| = 2$:

$$\left|Lg^\epsilon\right|(x) \le \left(\sum_{i=1}^d |b_i|c_{\epsilon,i} + \frac{1}{2}\sum_{i,k=1}^d |q_{ik}|c_{\epsilon,i,k}\right)\cdot g(x) \le c_\epsilon\left(|b|_{\ell^1} + |Q|_{\ell^1}\right)\cdot g(x).$$

The large-jump part is estimated using $|\alpha| = 0$ and the submultiplicativity of g:

$$\left|Kg^\epsilon(x)\right| \le c_\epsilon\int_{|y|\ge 1}\left(g(x)g(y) + g(x)\right)\nu(dy) = c_\epsilon\int_{|y|\ge 1}\left(g(y)+1\right)\nu(dy)\cdot g(x).$$

[2] We may replace this by the (strong) Markov property if $\sup_{y\in\mathbb{R}^d}\sup_{s\le T}\mathbb{E}^y[g(X_s - y)] < \infty$. For Lévy processes the first supremum is always trivial.

Using Taylor's formula with integral remainder term we can rewrite the part containing the small jumps and we see that

$$\begin{aligned}
|Jg^\epsilon(x)| &= \left| \sum_{i,k=1}^d \int_{0<|y|<1} \int_0^1 \partial_i\partial_k g^\epsilon(x+ty) y_i y_k (1-t)\, dt\, \nu(dy). \right| \\
&\le c_\epsilon \sum_{i,k=1}^d c_{\epsilon,i,k} \int_{0<|y|<1} \int_0^1 g(x+ty)|y_i y_k|(1-t)\, dt\, \nu(dy) \\
&\le c_\epsilon \sum_{i,k=1}^d c_{\epsilon,i,k} \int_{0<|y|<1} \int_0^1 g(ty)|y_i y_k|(1-t)\, dt\, \nu(dy) \cdot g(x) \\
&\le c'_\epsilon \sup_{|y|\le 1} g(y) \int_{0<|y|<1} |y|^2\, \nu(dy) \cdot g(x).
\end{aligned}$$

If we combine these three estimates, the claim follows. □

Proof of Theorem 3. We show a)⇒b)⇒c)⇒d)⇒e)⇒g)⇒h)⇒a) and c)⇒f)⇒a).([3]) Throughout the proof we will assume that $g \ge 1$ and $g \in C^2(\mathbb{R}^d)$. Otherwise we could replace g by its Friedrichs regularization g^ϵ, see Lemma 2, and $g+1$, resp., $g^\epsilon + 1$.

1° a) ⇒ b). If $\mathbb{E}[g(X_t)]$ is finite for some $t > 0$, then Lemma 5 shows that $\mathbb{E}[g(X_t)]$ is finite for all $t > 0$. For $a, b > 0$ we define a stopping time

$$\sigma := \sigma_{a,b} := \inf\left\{s \mid g(X_s) > cg(0)\mathrm{e}^{a+b}\right\}$$

and observe that we can use the subadditivity of g to get

$$\begin{aligned}
\mathbb{P}\left(g(X_t) > \mathrm{e}^a\right) &\ge \mathbb{P}\left(g(X_t) > \mathrm{e}^a,\ g(X_\sigma) \ge cg(0)\mathrm{e}^{a+b},\ \sigma \le t\right) \\
&\ge \mathbb{P}\left(g(X_\sigma - X_t) < g(0)\mathrm{e}^b,\ g(X_\sigma) \ge cg(0)\mathrm{e}^{a+b},\ \sigma \le t\right).
\end{aligned}$$

The strong Markov property yields (for all $t \le T$, T will be determined in the following step)

$$\begin{aligned}
\mathbb{P}\left(g(X_t) > \mathrm{e}^a\right) &\ge \int_{\sigma\le t} \mathbb{P}\left(g(-X_{t-\sigma(\omega)}) < g(0)\mathrm{e}^b\right) \mathbb{P}(d\omega) \\
&\ge \inf_{r\le t} \mathbb{P}\left(g(-X_r) < g(0)\mathrm{e}^b\right) \cdot \mathbb{P}(\sigma \le t) \\
&\ge \frac{1}{2}\mathbb{P}\left(\sup_{s\le t} g(X_s) > cg(0)\mathrm{e}^{a+b}\right).
\end{aligned}$$

In the last estimate we use that $\left\{\sup_{s\le t} g(X_s) > cg(0)\mathrm{e}^{a+b}\right\} \subseteq \{\sigma \le t\}$. The factor $\frac{1}{2}$ comes from the fact that g is locally bounded and $\lim_{t\to 0} \mathbb{P}(|X_t| > \epsilon) = 0$ (continuity in probability), which shows that there is some $0 < T \le t_0$ such that

$$\mathbb{P}\left(g(-X_t) < g(0)\mathrm{e}^b\right) \ge \frac{1}{2} \quad \text{for all } t \le T.$$

This proves that for $\mathrm{e}^\gamma := cg(0)\mathrm{e}^b$

$$\mathbb{P}\left(\sup_{s\le T} g(X_s) > \mathrm{e}^{a+\gamma}\right) \le 2\mathbb{P}(g(X_T) > \mathrm{e}^a).$$

([3])A direct proof of e)⇒a) is given in the next section.

We can now use the layer-cake formula to see that

$$\begin{aligned}\mathbb{E}\left[\sup_{s\le T} g(X_s)\right] &= 1 + \int_1^\infty \mathbb{P}\left(\sup_{s\le T} g(X_s) > y\right)\, dy \\ &= 1 + \mathrm{e}^\gamma \int_{-\gamma}^\infty \mathbb{P}\left(\sup_{s\le T} g(X_s) > \mathrm{e}^\gamma \mathrm{e}^a\right) \mathrm{e}^a\, da \\ &\le 1 + \mathrm{e}^\gamma \int_{-\gamma}^0 \mathrm{e}^a\, da + 2\mathrm{e}^\gamma \int_0^\infty \mathbb{P}\left(g(X_T) > \mathrm{e}^a\right) \mathrm{e}^a\, da \\ &\le \mathrm{e}^\gamma + 2\mathrm{e}^\gamma \mathbb{E}\left[g(X_T)\right].\end{aligned}$$

Using Lemma 5 we see that $\mathbb{E}\left[\sup_{s\le nT} g(X_s)\right] < \infty$ for all $n \in \mathbb{N}$, i.e. b) holds for all $t > 0$.

2° b) $\Rightarrow$ c). If $\sup_{s\le t} g(X_s)$ is integrable for some $t > 0$, then it is integrable for all $t > 0$, cf. Lemma 5. For fixed $t > 0$, let $\sigma \in \mathcal{T}$ be a stopping time with $\sigma \le t$, then

$$g(X_\sigma) \le \sup_{r\le t} g(X_r) \in L^1(\mathbb{P}).$$

Consequently, the family $\{g(X_\sigma)\}_{\sigma\in\mathcal{T},\sigma\le t}$ is dominated by the integrable random variable $\sup_{r\le t} g(X_r)$; hence, it is uniformly integrable.

3° c) $\Rightarrow$ d). This is immediate from the fact uniform integrability implies boundedness in L^1.

4° d) $\Rightarrow$ e). We rearrange (7) and insert it into (6) to get

$$\begin{aligned}&\mathbb{E}\left[(g\chi_R)(X_{t\wedge\tau_R})\right] - \mathbb{E}\left[\int_{[0,t\wedge\tau_R)} (L+J)g(X_s)\, ds\right] \\ &\quad= g(0) + \mathbb{E}\left[\int_{[0,t\wedge\tau_R)} \int_{|y|\ge 1} \left(g\chi_R(X_s+y) - g(X_s)\right) \nu(dy)\, ds\right] \\ &\quad= g(0) + \mathbb{E}\left[\int_{[0,t\wedge\tau_R)} \int_{|y|\ge 1} g\chi_R(X_s+y)\, \nu(dy)\, ds\right] - \nu(|y|\ge 1)\cdot \mathbb{E}\left[\int_{[0,t\wedge\tau_R)} g(X_s)\, ds\right].\end{aligned}$$

Now we use Lemma 6 for the Lévy generator $L + J$ and the estimates

$$\mathbb{E}\left[\int_{[0,t\wedge\tau_R)} g(X_s)\, ds\right] \le \int_{[0,t)} \mathbb{E}\left[g(X_s)\right] ds \le t \sup_{s\le t} \mathbb{E}\left[g(X_s)\right]$$

and

$$\mathbb{E}\left[(g\chi_R)(X_{t\wedge\tau_R})\right] \le \mathbb{E}\left[g(X_{t\wedge\tau_R})\right] \le \sup_{\sigma\in\mathcal{T},\sigma\le t} \mathbb{E}\left[g(X_\sigma)\right].$$

Because of our assumption d), there is a constant C_t, not depending on R, such that

$$C_t \ge \mathbb{E}\left[\int_{[0,t\wedge\tau_R)} \int_{|y|\ge 1} g\chi_R(X_s+y)\, \nu(dy)\, ds\right].$$

Letting $R \to \infty$, Fatou's lemma and yet another application of submultiplicativity yield

$$\begin{aligned} C_t &\geq \mathbb{E}\left[\int_{[0,t)} \int_{|y|\geq 1} g(X_s + y)\, \nu(dy)\, ds\right] \\ &\geq \frac{1}{c}\mathbb{E}\left[\int_{[0,t)} \int_{|y|\geq 1} \frac{g(y)}{g(-X_s)}\, \nu(dy)\, ds\right] \\ &\geq \frac{1}{c} \iint_{|X_s|\leq \epsilon} \frac{d\mathbb{P}\, ds}{g(-X_s)} \cdot \int_{|y|\geq 1} g(y)\, \nu(dy). \end{aligned}$$

Since g is locally bounded and $s \mapsto X_s$ is càdlàg, e) follows.

5° e) $\Rightarrow$ g). Let $\phi \in C_c^\infty(\mathbb{R}^d)$. The reflection $\widetilde{\phi}(x) := \phi(-x)$ is again in $C_c^\infty(\mathbb{R}^d)$ and thus $\|A^*\widetilde{\phi}\|_\infty < \infty$ by the representation of A^* as an integro-differential operator (2) and Taylor's formula. Choose $R > 0$ such that $\operatorname{supp}\phi$ is contained in the ball $B_R(0)$, then

$$(A^*\widetilde{\phi})(-x) = \int_{y\neq 0} \phi(x-y)\, \nu(dy), \quad |x| \geq 2R.$$

Since g is bounded on compact sets, it follows that

$$\begin{aligned} \int_{\mathbb{R}^d} g(x)|(A^*\widetilde{\phi})(x)|\, dx &= \left(\int_{|x|\leq 2R} + \int_{|x|>2R}\right) g(x)\, |(A^*\widetilde{\phi})(x)|\, dx \\ &\leq |B_{2R}(0)| \sup_{|x|\leq 2R} g(x) \|A^*\widetilde{\phi}\|_\infty + \int_{|x|>2R} \int_{y\neq 0} g(x)|\phi(x-y)|\, \nu(dy)\, dx. \end{aligned}$$

It remains to show that the integral expression on the right-hand side is finite. By Tonelli's theorem and a change of variables ($z = x - y$),

$$I := \int_{|x|>2R} \int_{y\neq 0} g(x)|\phi(x-y)|\, \nu(dy)\, dx = \int\int \mathbb{1}_{|z+y|>2R}\mathbb{1}_{|z|\leq R}|\phi(z)|g(z+y)\, dz\, \nu(dy),$$

where we use that $\operatorname{supp}\widetilde{\phi} \subseteq B_R(0)$. The elementary estimate $\mathbb{1}_{|z+y|>2R}\mathbb{1}_{|z|\leq R} \leq \mathbb{1}_{|y|\geq R}$ and the submultiplicativity of g now yield

$$I \leq c\left(\int_{|z|\leq R} |\phi(z)|\, g(z)\, dz\right)\left(\int_{|y|\geq R} g(y)\, \nu(dy)\right) < \infty;$$

the integrals are finite because of e) and the local boundedness of g, ϕ.

6° g) $\Rightarrow$ h). Trivial.

7° h) $\Rightarrow$ a). This part of the proof draws from a work by Hulanicki [3]. Take $\phi \in C_c^\infty(\mathbb{R}^d)$ non-negative such that $\phi \not\equiv 0$ and $A^*\phi \in L^1(\mathbb{R}^d, g)$. Let us first assume that g is bounded. Set

$$h(t) := \int_{\mathbb{R}^d} (P_t\phi)(-x) g(x)\, dx, \quad t \geq 0,$$

where $(P_t u)(x) = \mathbb{E}[u(x + X_t)]$ is the semigroup. We want to show that $|h'(t)| \leq Ch(t)$ for some constant $C > 0$. An application of Tonelli's theorem and a change of variables yield

$$\begin{aligned} \int_{\mathbb{R}^d} |P_t A\phi(-x)| g(x)\, dx &\leq \mathbb{E}\left[\int_{\mathbb{R}^d} |(A\phi)(-y)|\, g(y + X_t)\, dy\right] \\ &\leq c\mathbb{E}\left[g(X_t)\right] \int_{\mathbb{R}^d} |(A^*\phi)(y)| g(y)\, dy < \infty; \end{aligned}$$

the latter integral is finite because $A^*\phi \in L^1(\mathbb{R}^d, g)$ and g is bounded. Moreover, Dynkin's formula (3) entails that $\frac{d}{dt}P_t\phi = P_tA\phi$. Consequently, we can use the differentiation lemma for parameter-dependent integrals, cf. [7, Proposition A.1], to obtain

$$h'(t) = \int_{\mathbb{R}^d} \frac{d}{dt}(P_t\phi)(-x)g(x)\,dx = \int_{\mathbb{R}^d} (P_tA\phi)(-x)g(x)\,dx$$

and, by the above estimate,

$$|h'(t)| \le c\mathbb{E}\,[g(X_t)] \int_{\mathbb{R}^d} |(A^*\phi)(y)|g(y)\,dy.$$

The submultiplicativity of g gives

$$\left(\int_{\mathbb{R}^d} \frac{\phi(x)}{g(x)}\,dx\right) g(y) \le c\int_{\mathbb{R}^d} \phi(x)g(y-x)\,dx = c(\phi * g)(y)$$

for all $y \in \mathbb{R}^d$, i.e.

$$g(y) \le \frac{c}{\|\phi\|_{L^1(\mathbb{R}^d,1/g)}}(\phi * g)(y); \tag{10}$$

note that

$$\|\phi\|_{L^1(\mathbb{R}^d,1/g)} = \int_{\mathbb{R}^d} \frac{\phi(x)}{g(x)}\,dx \in (0,\infty)$$

because $g \ge 1$ is locally bounded and $\phi > 0$ on a set of positive Lebesgue measure. Using (10) for $y = X_t$, we get

$$|h'(t)| \le C\mathbb{E}[(\phi * g)(X_t)] = C\int_{\mathbb{R}^d} \mathbb{E}[\phi(X_t - x)]g(x)\,dx = Ch(t).$$

Hence, by Gronwall's lemma,

$$h(t) \le h(0)\mathrm{e}^{\alpha t}, \qquad t \ge 0,$$

for some constant $\alpha \ge 0$. Invoking once more (10), we conclude that

$$\mathbb{E}[g(X_t)] \le c'\mathbb{E}[(\phi * g)(X_t)] = c'h(t) \le c'h(0)\mathrm{e}^{\alpha t}.$$

So far, we assumed that g is bounded. For unbounded g, we replace g by $\min\{g, n\}$ – which is again submultiplicative – in the above estimates and find that

$$\mathbb{E}[\min\{g(X_t), n\}] \le c''\mathrm{e}^{\alpha t}$$

for some constant $c'' > 0$ not depending on $n \in \mathbb{N}$. Thus, by Fatou's lemma, $\mathbb{E}[g(X_t)] \le c''\mathrm{e}^{\alpha t}$ for all $t \ge 0$.

8° c) ⇒ f). Let $f \in L^1(\mathbb{R}^d, g)$. We see that

$$\begin{aligned}\int_{\mathbb{R}^d} |P_t^* f(x)|\, g(x)dx &\le \mathbb{E}\left[\int_{\mathbb{R}^d} |f(x - X_t)|\, g(x - X_t + X_t)dx\right] \\ &\le c\mathbb{E}\,[g(X_t)]\, \|f\|_{L^1(\mathbb{R}^d,g)},\end{aligned}$$

which shows that $P_t^* : L^1(\mathbb{R}^d, g) \to L^1(\mathbb{R}^d, g)$ is continuous. Let $\phi \in C_c(\mathbb{R}^d)$ and assume that $\operatorname{supp}\phi$ is contained in some ball $B_R(0)$ with radius $R > 0$. We show that $P_t^*\phi \to \phi$ in

$L^1(\mathbb{R}^d, g)$ as $t \to 0$. Since ϕ is uniformly continuous, we can pick $\epsilon = \epsilon(\eta) > 0$ in such a way that $|\phi(x+y) - \phi(x)| \le \eta$ for all x. Thus,

$$\begin{aligned}
&\int_{\mathbb{R}^d} |P_t^*\phi(x) - \phi(x)|\, g(x)dx \le \mathbb{E}\left[\int_{\mathbb{R}^d} |\phi(x - X_t) - \phi(x)|\, g(x)dx\right] \\
&= \mathbb{E}\left[\int_{B_{R+\epsilon}(0)} |\phi(x - X_t) - \phi(x)| \mathbb{1}_{|X_t|<\epsilon}\, g(x)dx\right] + \int_{\mathbb{R}^d} \mathbb{E}\left[|\phi(x - X_t) - \phi(x)| \mathbb{1}_{|X_t|\ge\epsilon}\right] g(x)dx \\
&\le |B_{R+\epsilon}(0)| \sup_{|x|<R+\epsilon} g(x) \cdot \eta + \mathbb{P}(|X_t| \ge \epsilon) \|\phi\|_{L^1(\mathbb{R}^d,g)} + c\,\mathbb{E}\left[g(X_t)\mathbb{1}_{|X_t|\ge\epsilon}\right] \|\phi\|_{L^1(\mathbb{R}^d,g)}.
\end{aligned}$$

Since $(g(X_t))_{t\le 1}$ is uniformly integrable, $X_t \to 0$ in probability, and $\eta > 0$ is arbitrary, we obtain that $\|P_t^*\phi - \phi\|_{L^1(\mathbb{R}^d,g)} \to 0$ as $t \to 0$. Using that $C_c(\mathbb{R}^d)$ is a dense subset of $L^1(\mathbb{R}^d, g)$, we conclude that $(P_t^*)_{t\ge 0}$ is a strongly continuous operator semigroup on $L^1(\mathbb{R}^d, g)$.

9° f) $\Rightarrow$ a). Let $\phi \in C_c(\mathbb{R}^d) \cap L^1(\mathbb{R}^d, g)$ such that $\phi \ge 0$ and $\phi = 1$ on $B_1(0)$. Using $g \ge 1$ and the submultiplicative property of g, we see that

$$\|P_t^*\phi\|_{L^1(\mathbb{R}^d,g)} = \mathbb{E}\left[\int_{\mathbb{R}^d} (g(x + X_t))\phi(x)dx\right] \ge \frac{1}{c}\mathbb{E}\left[g(X_t)\right] \int_{\mathbb{R}^d} \frac{\phi(x)\,dx}{g(-x)};$$

this implies that $\mathbb{E}\left[g(X_t)\right] < \infty$. □

The proof of Theorem 3 contains the following moment result for Lévy processes with bounded jumps. Alternate proofs can be found in Sato [9, Theorem 25.3, p. 159] or [5, Lemma 8.2]. If we use in Step 3° the submultiplicative function $g(x) := \mathrm{e}^{\beta|x|}$, $\beta > 0$, $x \in \mathbb{R}^d$, we get the following corollary.

Corollary 7. *Let $Y = (Y_t)_{t\ge 0}$ be a Lévy process whose jumps are uniformly bounded. Then Y has exponential moments, i.e. $\mathbb{E}\left[\mathrm{e}^{\beta|Y_t|}\right] < \infty$ for all $\beta > 0$ and $t \ge 0$.*

If Y has a non-degenerate jump part, then moments of the type $\mathbb{E}\left[\mathrm{e}^{\beta|X_t|^{1+\epsilon}}\right]$ do not exist, cf. [2, Theorem 3.3(c)].

2. Doob's condition (DL) for Lévy processes

Let Y be a stochastic process and $\mathcal{T}$ be the family of all stopping times with respect to the natural filtration of Y. Recall that Y *satisfies the condition* (DL) if for each fixed $t > 0$ the family $(Y_{t\wedge\sigma})_{\sigma\in\mathcal{T}}$ is uniformly integrable, i.e. if

$$\text{(DL)} \qquad \forall t > 0 \;:\quad \lim_{R\to\infty} \sup_{\sigma\in\mathcal{T}} \int |Y_{t\wedge\sigma}| \mathbb{1}_{|Y_{t\wedge\sigma}|\ge R}\, d\mathbb{P} = 0.$$

It is well known, cf. [8, Proposition IV.1.7, p. 124], that a local martingale is a martingale if, and only if, it is of class DL.

As a direct consequence of Theorem 3, we get the following characterization of the condition (DL) for functions of a Lévy process.

Theorem 8. *Let $X = (X_t)_{t\ge 0}$ be a Lévy process with triplet (b, Q, ν) and g a locally bounded submultiplicative function. The following assertions are equivalent.*

a) *The process $(g(X_t))_{t\ge 0}$ satisfies the condition* (DL)*;*
b) $\mathbb{E}[g(X_t)]$ *is finite for some $t > 0$;*
c) $\int_{|y|\ge 1} g(y)\,\nu(dy) < \infty$.

Corollary 9. *Let X be a Lévy process and $f : \mathbb{R}^d \to \mathbb{R}$ such that $|f(x)| \le g(x)$ for some locally bounded submultiplicative function g. If $\mathbb{E}\left[g(X_t)\right] < \infty$ and if $(f(X_t))_{t\ge 0}$ is a local martingale, then $(f(X_t))_{t\ge 0}$ is a martingale.*

Proof. Theorem 8 shows that $(g(X_t))_{t\geq 0}$, hence $(f(X_t))_{t\geq 0}$ enjoys the property (DL); therefore the local martingale $(f(X_t))_{t\geq 0}$ is already a proper martingale. □

The setting of Corollary 9 is quite natural if one thinks of Itô's formula or the expression (4) appearing in the discussion of Dynkin's formula: If A is the (pointwise extension to C^2 of the) generator of X, and if $Af = 0$, then $f(X_t)$ is, by Itô's formula, a local martingale. Corollary 9 thus gives a condition when this local martingale is a true martingale.

A direct proof that Theorem 8.c) entails b). Sometimes it is useful to have a direct proof that existence of the moments of the Lévy measure give generalized moments for the process. The approach below gives a method using standard 'household' techniques from any course on Markov processes, notably Dynkin's formula and Gronwall's inequality; therefore it applies to more general (strong) Markov processes.

*Alternative proof for Theorem 8.*c)⇒ b) *resp. Theorem 3.*e)⇒ a). In view of Lemma 2 we may replace g by its regularization g^ϵ. Combining Dynkin's inequality (Lemma 1) and the estimate from Lemma 6 shows

$$\mathbb{E}\left[g^\epsilon(X_{t\wedge\sigma})\right] \leq g^\epsilon(0) + C^{b,Q,\nu}_{\epsilon,g}\mathbb{E}\left[\int_{[0,t\wedge\sigma)} g(X_s)\,ds\right].$$

The constant C depends on ϵ, the triplet (b,Q,ν) and on $\int_{|y|\geq 1} g(y)\,\nu(dy)$, see Lemma 6. If we replace σ by $\sigma\wedge\tau_R$ with $\tau_R = \inf\{s\geq 0 \mid |X_s|\geq R\}$ and set $\kappa_R := \sup_{|y|\leq R} g(y)$, then we get

$$\begin{aligned}\mathbb{E}\left[g^\epsilon(X_{t\wedge\sigma\wedge\tau_R})\wedge\kappa_R\right] &\leq g^\epsilon(0) + C^{b,Q,\nu}_{\epsilon,g}\mathbb{E}\left[\int_{[0,t\wedge\sigma\wedge\tau_R)} g(X_s)\wedge\kappa_R\,ds\right]\\ &\leq g^\epsilon(0) + \tilde{C}^{b,Q,\nu}_{\epsilon,g}\int_{[0,t)}\mathbb{E}\left[g^\epsilon(X_{s\wedge\sigma\wedge\tau_R})\wedge\kappa_R\right]\,ds.\end{aligned}$$

We may now appeal to Gronwall's lemma and find

$$\mathbb{E}\left[g^\epsilon(X_{t\wedge\sigma\wedge\tau_R})\wedge\kappa_R\right] \leq g^\epsilon(0)\mathrm{e}^{tC^{b,Q,\nu}_{\epsilon,g}}$$

and an application of Fatou's lemma on the left-hand side proves $\mathbb{E}\left[g^\epsilon(X_{t\wedge\sigma})\right] < \infty$, and b) follows, if we take $\sigma\equiv t$. □

3. Martingale methods for Lévy processes

Let us give a further application of Theorem 3 to the recurrence/transience behaviour of Lévy processes. As a warm-up and in order to illustrate the method, we begin with a very short proof for the characterization of infinitely divisible random variables taking values in a lattice; the result as such is, of course, well-known (Sato [9, Section 24]). Recall that a random variable Y is infinitely divisible if, and only if, there is a Lévy process $(X_t)_{t\geq 0}$ such that $Y\sim X_1$.

Theorem 10. *Let $(X_t)_{t\geq 0}$ be a one-dimensional Lévy process with characteristic exponent ψ and triplet (b,Q,ν), see* (1)*. The following assertions are equivalent (for fixed $\beta\neq 0$)*

a) $\psi(\beta) = \mathrm{i}\alpha$ *for some* $\alpha\in\mathbb{R}$..
b) $\left|\mathbb{E}\left[\mathrm{e}^{\mathrm{i}\beta X_t}\right]\right| = 1$ *for some, hence for all,* $t>0$.
c) $X_{t_0}+\gamma$ *takes values in the lattice* $2\pi\beta^{-1}\mathbb{Z}$ *for some* $t_0>0$.
d) $X_t + \alpha\beta^{-1}t$ *takes values in the lattice* $2\pi\beta^{-1}\mathbb{Z}$ *for some* $\alpha\in\mathbb{R}$ *and all* $t>0$.
e) $\operatorname{supp}\nu\subset 2\pi\beta^{-1}\mathbb{Z}$ *and* $Q=0$ *and* $b = -\alpha\beta^{-1} + 2\pi\beta^{-1}\sum_{|k|<\beta(2\pi)^{-1}} k\nu(\{2\pi\beta^{-1}k\})$.

Remark 11. Our proof shows that there is also a connection between γ and α in Theorem 10.c) and d). If we use $t = t_0$ in d), it holds that $\gamma \in \alpha\beta^{-1}t_0 + 2\pi\beta^{-1}\mathbb{Z}$.

Proof. a)⇒b). This follows from $\mathbb{E}\left[e^{i\beta X_t}\right] = e^{-t\psi(\beta)}$ for any $t > 0$.

b)⇒c). We fix $t_0 > 0$ such that $\left|\mathbb{E}\left[e^{i\beta X_{t_0}}\right]\right| = 1$ and apply Lemma 12 to $X = \beta X_{t_0}$. This shows that there exists some $\gamma \in \mathbb{R}$ such that X is supported in $2\pi\beta^{-1}\mathbb{Z} - \gamma$.

c)⇒d). Let $t_0 > 0$ be as in c) and $t > 0$, $t \neq t_0$. We see that $\mathbb{E}\left[e^{i\beta X_t}\right] = (e^{-t_0\psi(\beta)})^{t/t_0}$. As $|e^{-t_0\psi(\beta)}| = 1$, we know that $\psi(\beta) \in i\mathbb{R}$. Lemma 12 shows that X_t is supported in $2\pi\beta^{-1}\mathbb{Z} + it\psi(\beta)\beta^{-1}$ for every $t > 0$.

d)⇒e). Let $t > 0$. A direct calculation shows that

$$\mathbb{E}\left[e^{i\beta X_t}\right] = \sum_{k\in\mathbb{Z}} e^{i2\pi k - i\alpha t}\mathbb{P}(X_t = 2\pi\beta^{-1}k - \alpha\beta^{-1}t) = e^{-i\alpha t}.$$

On the other hand, infinite divisibility entails

$$e^{-i\alpha t} = \mathbb{E}\left[e^{i\beta X_t}\right] = e^{-t\psi(\beta)} \quad \text{for all } t > 0.$$

This is only possible if $\psi(\beta) = i\alpha$. Comparing this with the Lévy–Khintchine formula (1), we infer that $b = -\alpha\beta^{-1} + 2\pi\beta^{-1}\sum_{|k|<\beta(2\pi)^{-1}} k\nu(\{2\pi\beta^{-1}k\})$, $Q = 0$ and $\operatorname{supp}\nu \subset 2\pi\beta^{-1}\mathbb{Z}$.

e)⇒a). This follows from the Lévy–Khintchine formula (1). □

The key step in the proof of Theorem 10 is the following lemma which is of independent interest.

Lemma 12. *Let X be a real random variable. If there exists $\beta \in \mathbb{R}\setminus\{0\}$ such that $\mathbb{E}\left[e^{i\beta X}\right] = e^{i\theta}$ for some $\theta \in \mathbb{R}$, then the distribution of X is supported on $2\pi\beta^{-1}\mathbb{Z} + \beta^{-1}\theta$.*

Proof. Without loss of generality we may assume that $\beta = 1$, i.e. $\left|\mathbb{E}\left[e^{iX}\right]\right| = 1$ or $\mathbb{E}\left[e^{i(X-\theta)}\right] = 1$ for some $\theta \in [0, 2\pi)$. Let $(X_i)_{i\in\mathbb{N}}$ be iid copies of the random variable X and define for every $n \in \mathbb{N}$

$$Y_n := \frac{1}{2^n}\prod_{k=1}^{n}(1 + \cos(X_k - \theta)) = \prod_{k=1}^{n}\frac{1 + \cos(X_k - \theta)}{2}.$$

Set $\mathcal{F}_n := \sigma(X_1, \dots, X_n)$ and note that $(Y_n)_{n\in\mathbb{N}}$ is adapted to this filtration. We see that

$$\mathbb{E}[Y_n \mid \mathcal{F}_{n-1}] = \mathbb{E}\left[\prod_{k=1}^{n}\frac{1 + \cos(X_k - \theta)}{2} \mid \mathcal{F}_{n-1}\right] = Y_{n-1}\frac{1 + \mathbb{E}\left[\cos(X_n - \theta)\right]}{2} = Y_{n-1},$$

so $(Y_n)_{n\in\mathbb{N}}$ is a discrete-time martingale. As $0 \le Y_n \le 1$ and $\mathbb{E}Y_n = 1$, we conclude that Y_n converges to 1 in L^1 and a.s. as $n \to \infty$. Thus, $Y_1 = \mathbb{E}[1|\mathcal{F}_1] = 1$ a.s., which implies that $X - \theta$ takes only values in the lattice $2\pi\mathbb{Z}$. □

Assume now that $(X_t)_{t\ge0}$ is a Lévy process with which admits an exponential moment of the form $\mathbb{E}\left[e^{\beta X_t}\right] < \infty$ for some $\beta \neq 0$. By Theorem 3, $\int_{|y|\ge1} e^{\beta y}\,\nu(dy) < \infty$, and it is easy to see from the Lévy–Khintchine formula (1) that the exponent ψ has a continuous continuation to all complex numbers $\xi + i\eta \in \mathbb{C}$ with $\xi \in \mathbb{R}$ and η between 0 and β. In particular,

$$\mathbb{E}\left[e^{\beta X_t}\right] = e^{-t\psi(-i\beta)}, \quad t > 0,$$

which shows that the sets $\left\{\beta \in \mathbb{R} \mid \mathbb{E}\left[e^{\beta X_t}\right] = 1\right\}$, $\left\{\beta \in \mathbb{R} \mid \forall t > 0 \ : \ \mathbb{E}\left[e^{\beta X_t}\right] = 1\right\}$ and $\{\beta \in \mathbb{R} \mid \psi(-i\beta) = 0\}$ coincide.

Theorem 13. *Let $(X_t)_{t\ge0}$ be a one-dimensional Lévy process and $A := \left\{\xi \in \mathbb{R} \mid \mathbb{E}\left[e^{\xi X_t}\right] = 1\right\}$. If $\beta \in A \setminus \{0\}$, then βX_t is transient.*

Proof. Define $Y_t = \mathrm{e}^{\beta X_t}$, with $\beta \in A \setminus \{0\}$. With a similar argument as in the proof of Lemma 12 we see that Y_t is a martingale. Since $t \mapsto \mathrm{e}^{\beta Y_t}$ is positive and right-continuous, the martingale convergence theorem shows that $\lim_{t\to\infty} Y_t = Y_\infty$ a.s. for some a.s. finite random variable Y_∞. As βX_t is again a Lévy process, we see that $\mathrm{e}^{\beta X_t}$ can only converge if $\beta X_t \to -\infty$ as $t \to \infty$; thus, βX_t cannot be recurrent. □

It is clear that Theorem 13 still holds for a d-dimensional Lévy process if we interpret ξX_t and βX_t as scalar products with $\xi, \beta \in \mathbb{R}^d$. By Cauchy's inequality, $|\beta \cdot X_t|/|\beta| \le |X_t|$, and so $\lim_{t\to\infty} |X_t| = \infty$, i.e. $(X_t)_{t\ge 0}$ is transient if $\beta \cdot X_t$ is transient.
