C. Lacroix et al, (Ed) Introduction to Frustrated Magnetism

1. Introduction and motivation

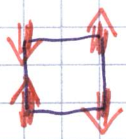
Frustration describes a situation

— where not all constraints can be simultaneously satisfied

— where not all contributions to the (potential) energy of a physical system can be simultaneously minimized

Example : Ising spins with antiferromagnetic nearest-neighbor coupling

vs.



6 degenerate inequivalent lowest-energy states

(frustrated)

2 degenerate symmetry-equivalent lowest-energy states

(unfrustrated)

Frustration tends to suppress (conventional) magnetic order.

Experimentally :

$$f = \frac{|\Theta_{CW}|}{T_N}$$ („frustration ratio") large

$\Theta_{CW} \hat{=}$ Curie-Weiss temperature $\left(\chi = \frac{C}{T-\Theta_{CW}}\right)$

$|\Theta_{CW}|$ measures magnitude of exchange interaction between moments

$T_N \hat{=}$ Néel temperature (ordering temperature)

Unfrustrated systems have $T_N \simeq |\Theta_{CW}| \sim f \approx 1$.

Alternative view: Soft fluctuations destroy order.

Frustration leads to massively degenerate ground-state manifolds at classical level.

Perturbation (e.g. quantum effects) then produce nontrivial states.

(Compare Quantum Hall effect: Landau level highly degenerate; interactions produce fractional QHE)

Why is frustrated magnetism interesting?

- Frustrated magnets can host a plethora of novel (exotic, interesting) states, both ordered and disordered.
  Many of those states have exotic excitations.
  (eg. spinons, monopoles, anyons, ...)

- Frustrated magnets can display interesting forms of topology (topological order, emergent gauge fields, long-range entanglement)

  2016 Nobel prize for topological physics

- Theory has found/proposed many non-trivial phases.
  Materials have been found/synthesized to realize those.
  Prospects for applications exist. (topological quantum computing, information storage, ...)

- Fertile links exist to other fields of research:
  Mathematical physics (→ topology),
  Statistical mechanics,
  High-temperature superconductivity.

Global challenges of the field

Systematic understanding of interacting topological phases

Diagnosis of topological / exotic phases

Finding / designing materials

Tuning materials and phenomena (eg. Mott FET)

Designing application concepts
