

Supplementary Note.

New Photos. Enhanced activation during emotional “remember” trials relative to new emotional photos was found in the right amygdala $t(12) = 2.26, P < 0.05$. No significant differences involving new photos were found in the parahippocampus and hippocampus. These regions have been shown to be involved in both encoding-related activity and retrieval-related activity during a recognition test (Stark & Okado, 2003). Assessment of new photos may result in more incidental encoding-related activity, while assessment of old photos may result in more retrieval related activity. Thus a comparison between old and new photos in the context of this task may yield nil results.
